January 22, 2015

# Context

- ▶ Beginning: october 2013
- ▶ Main supervisor: Bruno Hérault (CIRAD)
- ▶ Main objective: Capacity building on modelling through providing a spatialized model of future deforestation in the Guiana Shield

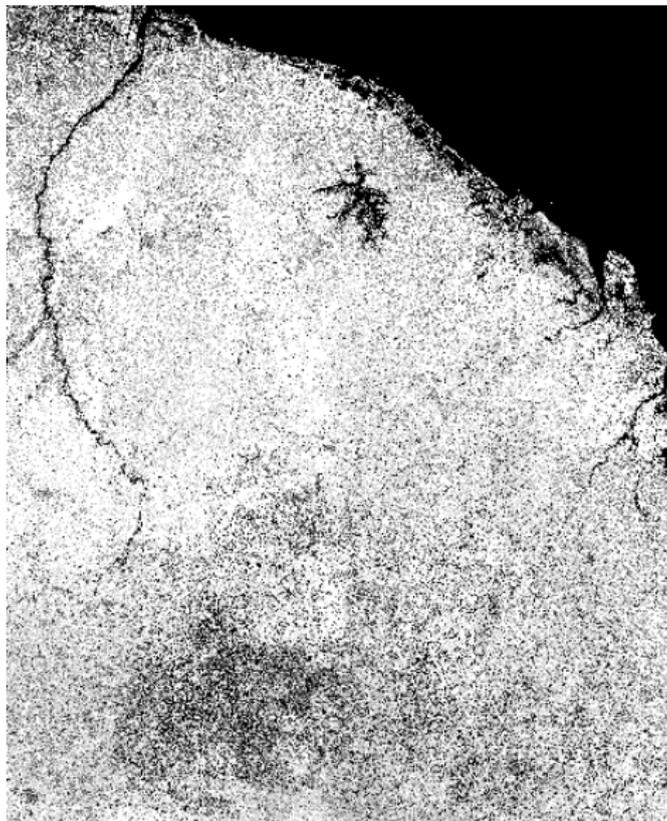

# Objectives

- ▶ Produce a map of probability of deforestation in French Guiana for the period 2004-2008 at 30 meters resolution
- ▶ Using simple, free and opensource softwares (R and GRASS)
- ▶ A simple model, with as little input data as possible

# Deforestation data

- ▶ Maps by Hansen et al. (2013) - U. of Maryland
- ▶ Forest cover 2000 and forest cover change 2001-2013
- ▶ Threshold forest cover = 75%
- ▶ Neighbouring filter (eliminate isolated pixels)

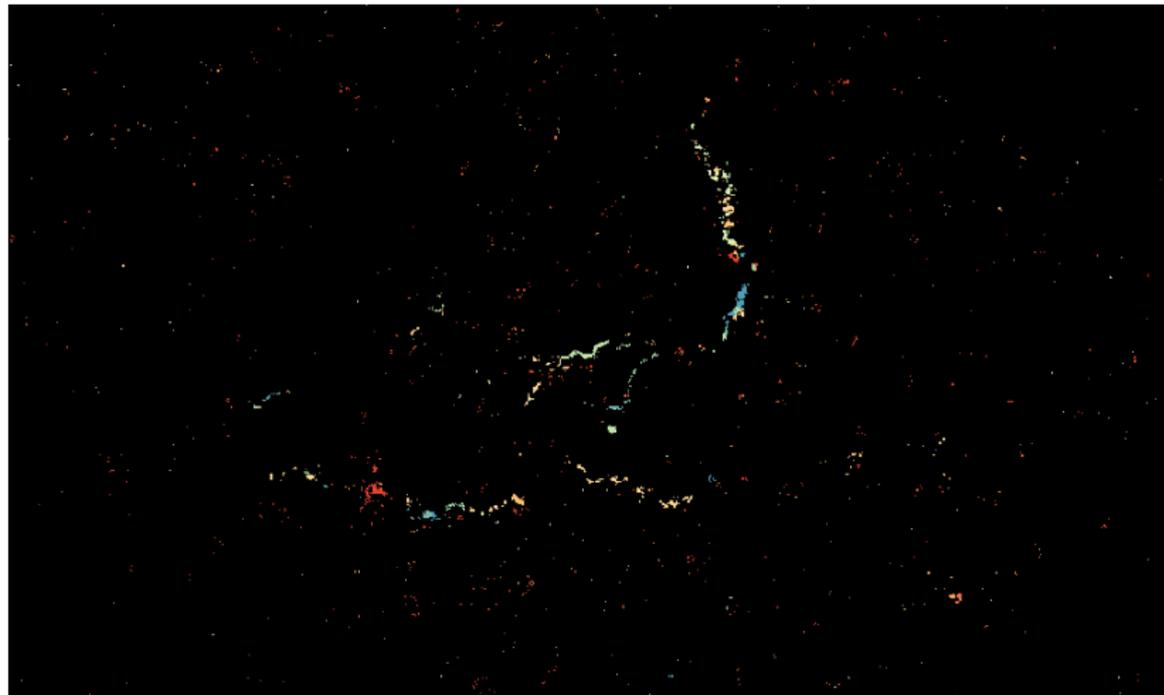

## Choosing an appropriate threshold and filtering: original forest cover 2000 data

## Choosing an appropriate threshold and filtering: final forest cover 2000 data

# Filtering forest cover change data : original deforestation map

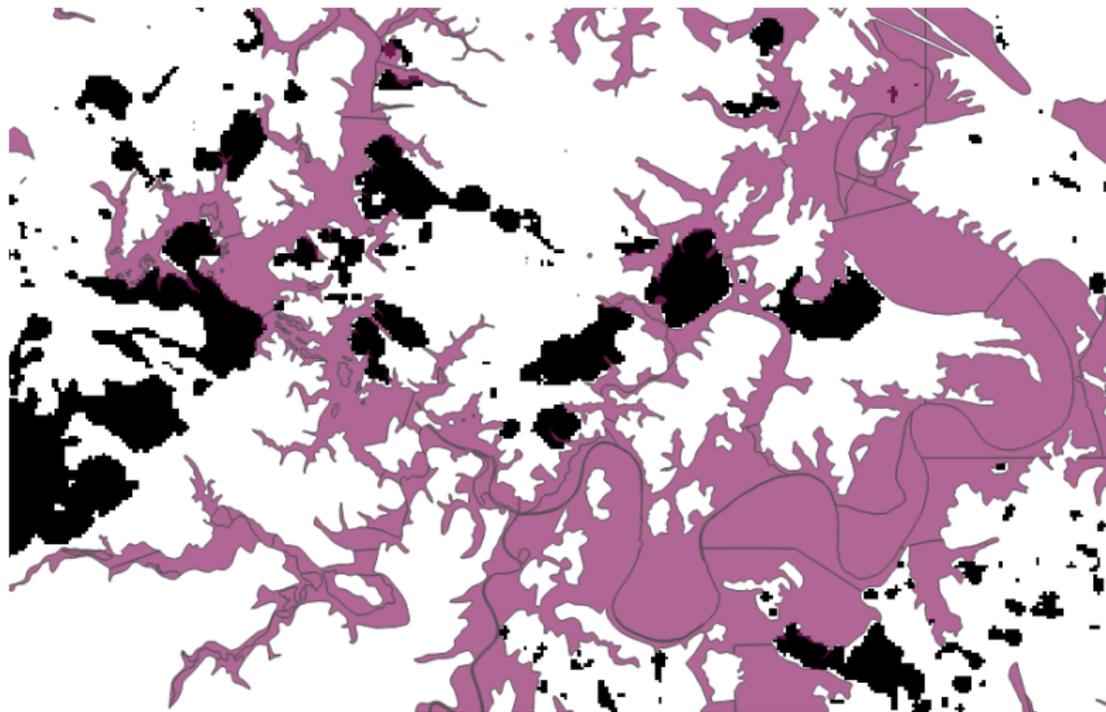

## Filtering forest cover change data : final deforestation map

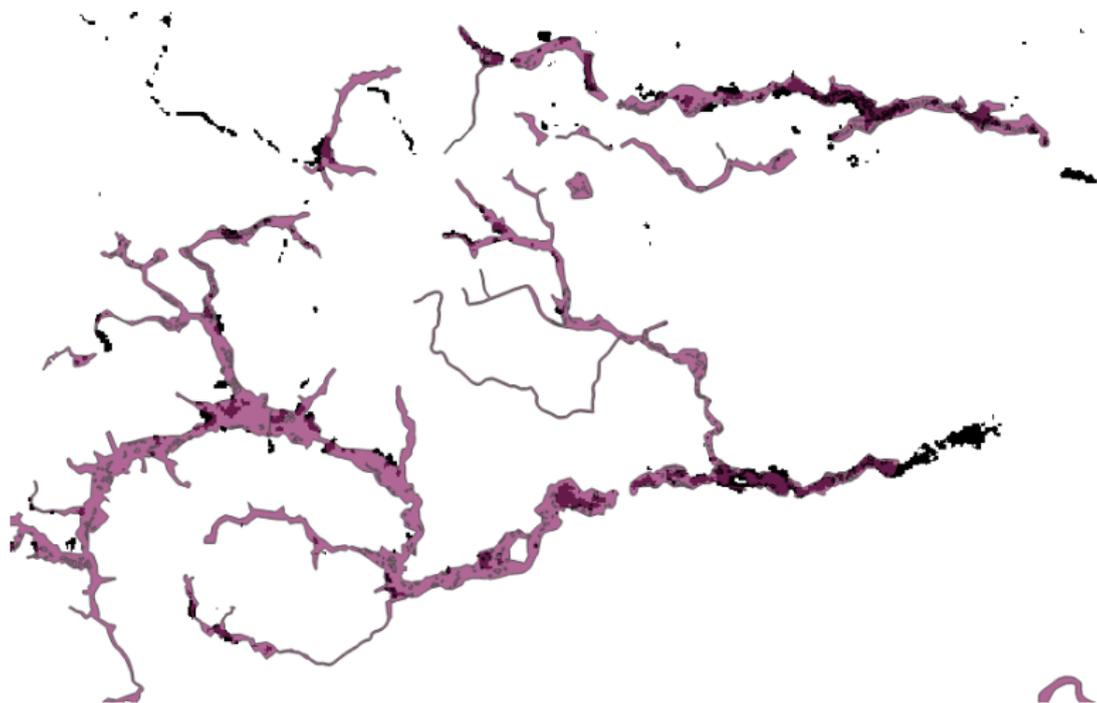

## Explanatory variables

- ▶ Distance to previous (2000-2004) deforestation (based only on Hansen data)
- ▶ Index of forest fragmentation (based only on Hansen data)
- ▶ Distance to closest road (2008 network)
- ▶ Distance to closest forest track (2008 network)
- ▶ Distance to main cities
- ▶ Protected areas
- ▶ Elevation (available at 90 meters resolution worldwide)
- ▶ Hydromorphy

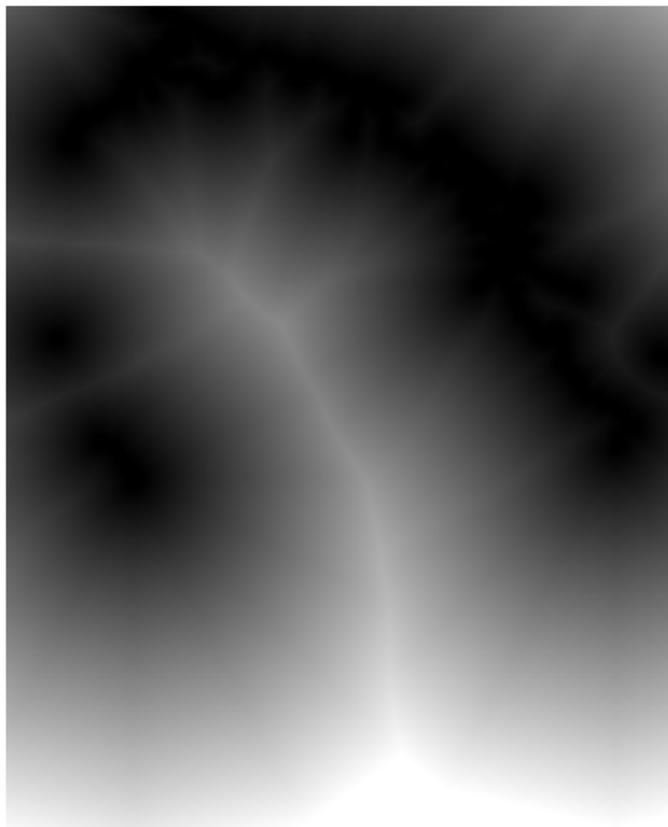

## Example: Deforestation and Hydromorphy in coastal area

## Example: Deforestation and Hydromorphy in gold mining area

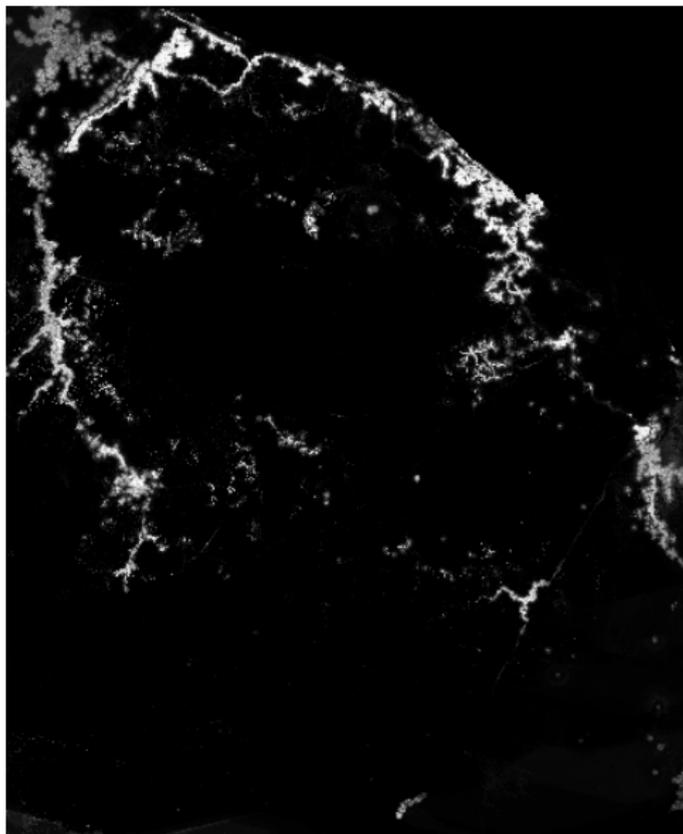

## Example: Distance to road (2008 network)

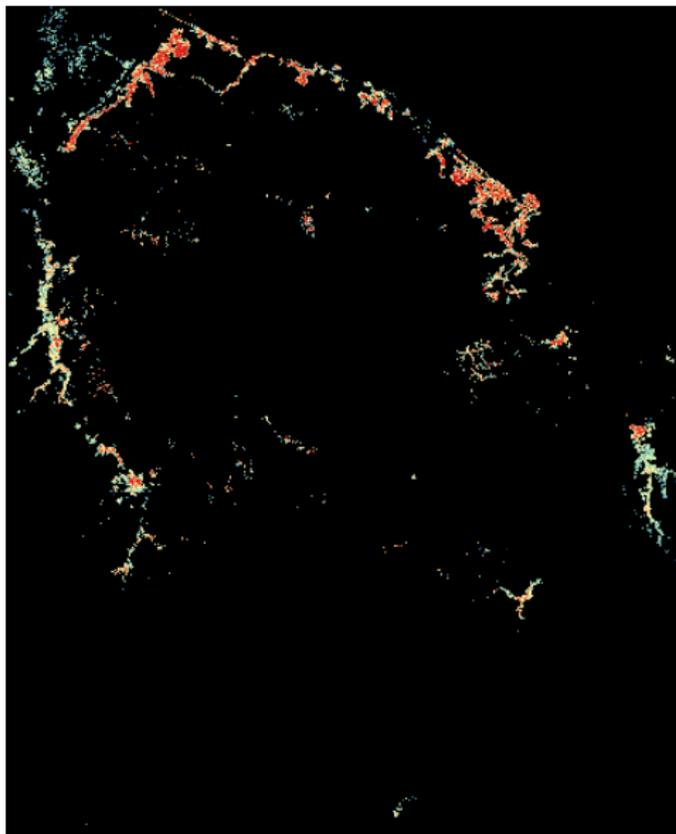

# Modelling the probability of deforestation: Random forest classification

- ▶ Widely used for forest cover mapping but never for deforestation modelling as far as we know
- ▶ Sampling: 50'000 deforested pixels during 2004-2008 (half of all deforested pixels) and 100'000 not-deforested pixels during 2004-2008 (a tiny fraction of all not-deforested pixels, but...)

# Results

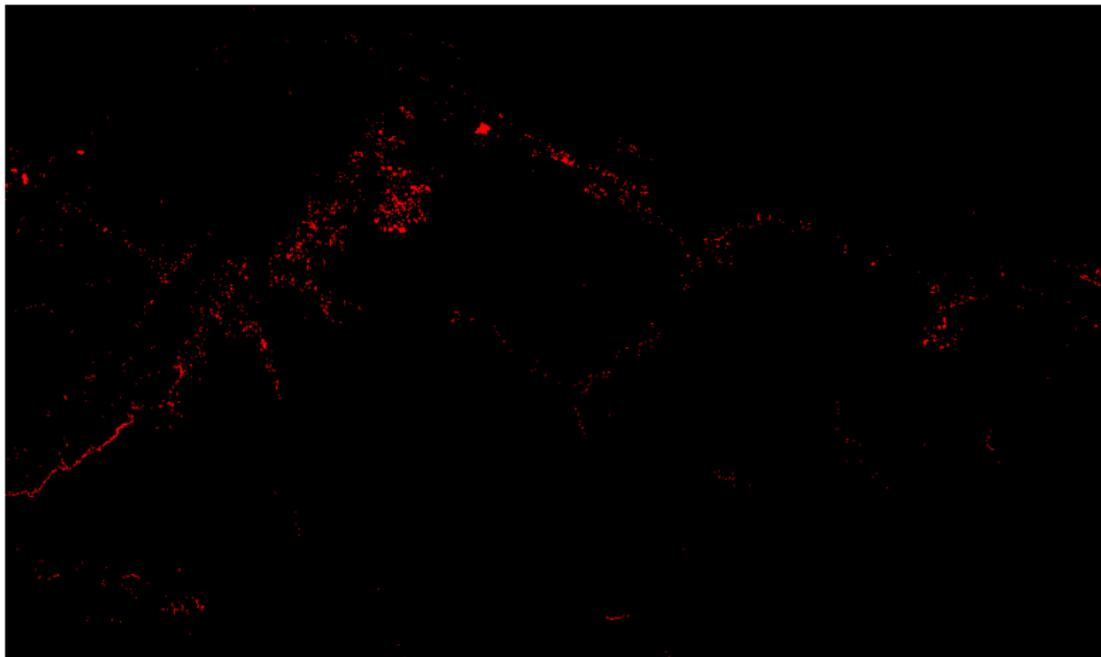

# Results

# Results

# Results

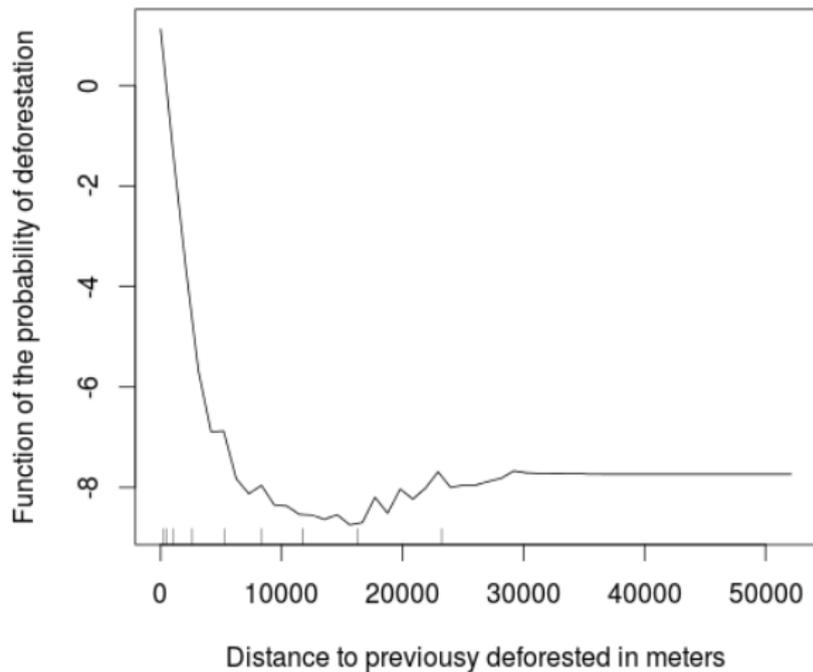

## Confusion matrix - First assessment of model's quality

- ▶ True negatives: 97'436 on 99'999 samples
- ▶ True positives: 49'333 on 50'000 samples
- ▶ False negatives and false positives: 2'537 and 667 (2.5 and 1.3% respectively)
- ▶ Validation on all pixels still to produce

# Deforestation and explanatory variables

Partial Dependence on "d\_prev\_def"

# Perspectives: coupling with the model of intensity of deforestation

- ▶ First part of the modelling process: model the intrinsic probability of deforestation (focus on geographic variables, no notion of quantity)
- ▶ The model of intensity of deforestation will define the number  $X$  of pixels to be deforested to reach a certain level of deforestation
- ▶ Pixels with highest probability of deforestation will be deforested first
- ▶ Relevant scale? Town?

# Modelling the intensity of deforestation: demography in French Guiana

- ▶ Population expected to double during the next 20 years, which impact on deforestation levels?
- ▶ Alternative scenarios: capacity of the different towns to implement their existing urban plannings to limit the magnitude of deforestation
- ▶ Need for a reflexion on the main drivers of the intensity of deforestation in the neighbouring countries
